Construction of Cyclic and Constacyclic Codes for b-symbol Read Channels Meeting the Plotkin-like Bound *

Minghui Yang, Jin Li, Keqin Feng

Abstract-The symbol-pair codes over finite fields have been raised for symbol-pair read channels and motivated by application of high-density data storage technologies [1, 2]. Their generalization is the code for b-symbol read channels ($b > 2$). Many MDS codes for b-symbol read channels have been constructed which meet the Singleton-like bound ([3, 4, 10] for $b = 2$ and [11] for $b > 2$). In this paper we show the Plotkin-like bound and present a construction on irreducible cyclic codes and constacyclic codes meeting the Plotkin-like bound.

keywords-Symbol-pair codes, b-symbol read channel, Plotkin bound, codes for magnetic storage, cyclic codes.

1 Introduction

Let $\mathbb{F}_q$ be the finite field with q elements. For $n \geq 3$ and $2 \leq b \leq n-1$, we define the following "b-symbol read" $\mathbb{F}_q$-linear mapping

$$\pi_b : \mathbb{F}_q^n \to (\mathbb{F}_q^b)^n$$

$$\boldsymbol{x} = (x_0, x_1, \ldots, x_{n-1}) \to \pi_b(\boldsymbol{x}) = (\boldsymbol{x}_{[b]}, \sigma(\boldsymbol{x}_{[b]}), \ldots, \sigma^{n-1}(\boldsymbol{x}_{[b]}))$$

where $\boldsymbol{x}_{[b]} = (x_0, x_1, \ldots, x_{b-1})$ and the "b-symbols"

$$\sigma^i(\boldsymbol{x}_{[b]}) = (x_i, x_{i+1}, \ldots, x_{i+b-1}) \quad (0 \leq i \leq n-1)$$

are the "cyclic" shiftings of $\boldsymbol{x}_{[b]}$, where for $l \geq n, x_l = x_{l-n}$. The b-distance between $\boldsymbol{x}$ and $\boldsymbol{y} \in \mathbb{F}_q^n$ is defined as the Hamming distance between $\pi_b(\boldsymbol{x})$ and $\pi_b(\boldsymbol{y})$:

$$d_b(\boldsymbol{x}, \boldsymbol{y}) = d_H(\pi_b(\boldsymbol{x}), \pi_b(\boldsymbol{y})) = w_H(\pi_b(\boldsymbol{x}) - \pi_b(\boldsymbol{y})) = w_b(\boldsymbol{x} - \boldsymbol{y}),$$

where for $\boldsymbol{z} \in \mathbb{F}_q^n$, $w_b(\boldsymbol{z}) = w_H(\pi_b(\boldsymbol{z}))$ is called the b-weight of $\boldsymbol{z}$.

A subset C of $\mathbb{F}_q^n$ is called a code with parameters $(n, K, d_b)_q$, where $K = |C| \geq 2$ and

$$d_b = d_b(C) = \min\{d_b(c, c') : c, c' \in C, c \neq c'\}.$$

If C is a linear code, namely C is an $\mathbb{F}_q$-subspace of $\mathbb{F}_q^n$, then $K = q^k$, where $k = \dim_{\mathbb{F}_q} C \geq 1$ and $d_b = \min\{w_b(c) : 0 \neq c \in C\}$. For $b = 2$, C is called as symbol-pair code which is used for symbol-pair read channels and motivated by the application of high-density data storage technologies [1, 2]. The generalization for $b > 2$ [5] can be considered as error-correcting codes over b-symbol read channels. In fact, such codes were first introduced even earlier by Levenshtein [6-8] as the sequence reconstruction problem and used in molecular biology and chemistry.

Basic properties of the codes for b-symbol read channels have been explored and several bounds have been given to judge the goodness of such codes [1, 2, 5, 9]. Several constructions of such codes have been presented, particularly for MDS codes which meet the Singleton-like bound [3, 4, 10, 11]. In this paper we consider the case where $d_b > \frac{n(q^b-1)}{q^b}$. In the next section we present a new bound for this case as an analogue of usual Plotkin bound [12, Theorem 5.2.4], and construct a series of irreducible cyclic codes and constacyclic codes $(n, K, d_b)_q$ such that their parameters meet the Plotkin-like bound.

2 A series of codes for b-symbol channel meeting the Plotkin-like bound

Firstly we show a new bound on codes for b-symbol channel.

Lemma 1 (Plotkin-like bound) Let $b \geq 2$ and C be a code for b-symbol channel with parameters $(n, K, d_b)_q$. If $d_b > n\theta_b$ where $\theta_b = \frac{q^b-1}{q^b}$, then

$$K \leq \frac{d_b}{d_b - n\theta_b}. \tag{1}$$

Moreover, if the code C meets this bound, namely the inequality (1) is an equality then C is an equi-b-distance code. Namely, for any distinct codewords c and c' in C, $d_b(c, c') = d_b(= \frac{Kn\theta_b}{K-1})$.

Proof. The proof of this Lemma is the same as the proof of [12], Theorem 5.2.4. We duplicate the proof for convenience of readers. Let $C = \{c^{(1)}, c^{(2)}, \ldots, c^{(K)}\}$ and consider the following $K \times n$ array over $\mathbb{F}_q^b$

$$A = \begin{pmatrix} \pi_b(c^{(1)}) \\ \vdots \\ \pi_b(c^{(K)}) \end{pmatrix} = \begin{pmatrix} c_{[b]}^{(1)} & \sigma(c_{[b]}^{(1)}) & \cdots & \sigma^{n-1}(c_{[b]}^{(1)}) \\ \vdots & \vdots & \cdots & \vdots \\ c_{[b]}^{(K)} & \sigma(c_{[b]}^{(K)}) & \cdots & \sigma^{n-1}(c_{[b]}^{(K)}) \end{pmatrix} = (a_{j\lambda}), a_{j\lambda} = \sigma^{\lambda}(c_{[b]}^{(j)}) \in \mathbb{F}_q^b.$$

Let $\mathbb{F}_q^b = \{v_1, v_2, \ldots, v_{q^b}\}$ and for each $j (1 \leq j \leq q^b)$, $m_{j\lambda}$ be the number of v_j appeared in λ-th column $(0 \leq \lambda \leq n-1)$. Then $\sum_{j=1}^{q^b} m_{j\lambda} = K$ for each λ and

$$\begin{aligned} K(K-1)d_b &\leq \sum_{1 \leq i \neq j \leq K} d_b(c^{(i)}, c^{(j)}) = \sum_{1 \leq i \neq j \leq K} d_H(\pi_b(c^{(i)}), \pi_b(c^{(j)})) \\ &= \sum_{\lambda=0}^{n-1} \sum_{j=1}^{q^b} m_{j\lambda}(K - m_{j\lambda}) = nK^2 - \sum_{\lambda=0}^{n-1} \sum_{j=1}^{q^b} m_{j\lambda}^2 \\ &\leq nK^2 - q^{-b} \sum_{\lambda=0}^{n-1} (\sum_{j=1}^{q^b} m_{j\lambda})^2 \\ &= nK^2 - q^{-b} nK^2 = n\theta_b K^2. \end{aligned}$$

Therefore $(K-1)d_b \leq n\theta_b K$ which implies the inequality (1). Moreover, if $(K-1)d_b = n\theta_b K$, then $d_b = \frac{1}{K(K-1)} \sum_{c,c' \in C, c \neq c'} d_b(c, c')$ which implies that C is an equi-b-distance code. □

Now we construct a series of irreducible cyclic codes over $\mathbb{F}_q$ meeting the Plotkin-like bound given by Lemma 1. We fix the following notations.

(A) p is a prime number, $f \geq 1, q = p^f$.
(B) $n \geq 2$, $\gcd(n, p) = 1$.
(C) s is the order of $q (\mathrm{mod} n)$. Namely, s is the smallest positive integer such that $q^s \equiv 1 (\mathrm{mod} n)$.
(D) $Q = q^s$, $\mathbb{F}_Q^* = \langle \gamma \rangle, Q - 1 = ne, \alpha = \gamma^e$, then the order of α is n and $\mathbb{F}_q(\alpha) = \mathbb{F}_Q$.
(E) $T_q^Q : \mathbb{F}_Q \to \mathbb{F}_q$ is the trace mapping from $\mathbb{F}_Q$ to $\mathbb{F}_q$. This is an $\mathbb{F}_q$-linear mapping.

We consider the following linear code over $\mathbb{F}_q$,

$$C = \{c_\beta = (T_q^Q(\beta), T_q^Q(\beta\alpha), \ldots, T_q^Q(\beta\alpha^{n-1})) \in \mathbb{F}_q^n : \beta \in \mathbb{F}_Q\}. \tag{2}$$

This is a cyclic code. The parity-check polynomial $h(x) \in \mathbb{F}_q[x]$ of C is the minimal (irreducible) polynomial of α^{-1} over $\mathbb{F}_q$. From the definition of s we know that $\dim_{\mathbb{F}_q} C = s (= \deg(h(x))$ and $K = |C| = q^s = Q$. The length of C is n.

Let $e' = \gcd(e, \frac{Q-1}{q-1}) = 1$. In the following result we consider the case of $e' = 1$. Since $e|Q-1$ and $Q = q^s$. It is easy to see that $e' = 1$ if and only if $e|q-1$ and $\gcd(e, s) = 1$.

Theorem 1 Let C be the code over $\mathbb{F}_q$ defined by (2). Assume that $e' = \gcd(e, \frac{Q-1}{q-1})$ is one (namely, $e|q-1$ and $\gcd(e, s) = 1$). Then for each $b (2 \leq b \leq s-1)$, the code C has parameters $[n, k, d_b]_q$ with $k = s, d_b = \frac{Q(q^b-1)}{eq^b}$ and meets the Plotkin-like bound given by Lemma 1.

Proof. Since C is an $\mathbb{F}_q$-linear code,

$$\begin{aligned} d_b = d_b(C) &= \min\{w_b(c) : 0 \neq c \in C\} \\ &= \min\{w_b(c_\beta) : \beta \in \mathbb{F}_Q^*\} = \min\{w_H(\pi_b(c_\beta)) : \beta \in \mathbb{F}_Q^*\} \end{aligned}$$

where

$$\pi_b(c_\beta) = ((c_\beta)_{[b]}, \sigma((c_\beta)_{[b]}), \ldots, \sigma^{n-1}((c_\beta)_{[b]}))$$

and

$$\sigma^\lambda((c_\beta)_{[b]}) = (T_q^Q(\beta\alpha^\lambda), T_q^Q(\beta\alpha^{\lambda+1}), \ldots, T_q^Q(\beta\alpha^{\lambda+b-1}) \in \mathbb{F}_q^b \ \ (0 \leq \lambda \leq n-1).$$

Therefore, for each $\beta \in \mathbb{F}_Q^*$, $w_H(\pi_b(c_\beta)) = n - N_\beta$, where

$$\begin{aligned} N_\beta &= \sharp\{\lambda : 0 \leq \lambda \leq n-1, T_q^Q(\beta\alpha^\lambda) = T_q^Q(\beta\alpha^{\lambda+1}) = \cdots = T_q^Q(\beta\alpha^{\lambda+b-1}) = 0\} \\ &= \sum_{\lambda=0}^{n-1} (\frac{1}{q} \sum_{y_0 \in \mathbb{F}_q} \zeta_p^{T_p^q(y_0 T_q^Q(\beta\alpha^\lambda))} \frac{1}{q} \sum_{y_1 \in \mathbb{F}_q} \zeta_p^{T_p^q(y_1 T_q^Q(\beta\alpha^{\lambda+1}))} \cdots \frac{1}{q} \sum_{y_{b-1} \in \mathbb{F}_q} \zeta_p^{T_p^q(y_{b-1} T_q^Q(\beta\alpha^{\lambda+b-1}))}) \\ &= \frac{1}{q^b} \sum_{\lambda=0}^{n-1} \sum_{y_0, \ldots, y_{b-1} \in \mathbb{F}_q} \zeta_p^{T_p^Q[\alpha^\lambda \beta(y_0 + y_1\alpha + \cdots + y_{b-1}\alpha^{b-1})]} \\ &= \frac{n}{q^b} + \frac{1}{q^b} \sum_{(0,\ldots,0) \neq (y_0,\ldots,y_{b-1}) \in \mathbb{F}_q^b} \sum_{x \in D} \zeta_p^{T_p^Q[x\beta(y_0 + y_1\alpha + \cdots + y_{b-1}\alpha^{b-1})]}, \end{aligned}$$

where $D = \langle\alpha\rangle = \langle\gamma^e\rangle$ is the subgroup of $\mathbb{F}_Q^*$ with order n. Let $\widehat{\mathbb{F}_Q^*}$ be the group of the multiplicative characters of $\mathbb{F}_Q$. We have, for $x \in \mathbb{F}_Q^*$,

$$\sum_{\substack{\chi \in \widehat{\mathbb{F}_Q^*} \\ \chi(D)=1}} \chi(x) = \begin{cases} e, & \text{if } x \in D \\ 0. & \text{otherwise} \end{cases}$$

Therefore

$$N_\beta = \frac{n}{q^b} + \frac{1}{q^b} \sum_{(0,\ldots,0)\neq(y_0,\ldots,y_{b-1})\in\mathbb{F}_q^b} \sum_{x\in\mathbb{F}_Q^*} \zeta_p^{T_p^Q[x\beta(y_0+y_1\alpha+\cdots+y_{b-1}\alpha^{b-1})]} \sum_{\substack{\chi\in\widehat{\mathbb{F}_Q^*}\\ \chi(D)=1}} \frac{1}{e}\chi(x)$$

$$= \frac{n}{q^b} + \frac{1}{eq^b} \sum_{(0,\ldots,0)\neq(y_0,\ldots,y_{b-1})\in\mathbb{F}_q^b} \sum_{\substack{\chi\in\widehat{\mathbb{F}_Q^*}\\ \chi(D)=1}} \overline{\chi}(\beta(y_0+y_1\alpha+\cdots+y_{b-1}\alpha^{b-1}))G_Q(\chi)$$

$$= \frac{n}{q^b} + \frac{1}{eq^b} \sum_{\substack{\chi\in\widehat{\mathbb{F}_Q^*}\\ \chi(D)=1}} \overline{\chi}(\beta)G_Q(\chi) \sum_{(0,\ldots,0)\neq(y_0,\ldots,y_{b-1})\in\mathbb{F}_q^b} \overline{\chi}(y_0+y_1\alpha+\cdots+y_{b-1}\alpha^{b-1}) \quad (3)$$

where $G_Q(\chi)$ is the Gauss sum over $\mathbb{F}_Q$ defined by

$$G_Q(\chi) = \sum_{x\in\mathbb{F}_Q^*} \chi(x)\zeta_p^{T_P^Q(x)}$$

and we use the following facts.

(I) From $\mathbb{F}_q(\alpha) = \mathbb{F}_Q$ and $2 \le b \le s-1, Q = q^s$ we know that $\{1, \alpha, \ldots, \alpha^{s-1}\}$ is a basis of $\mathbb{F}_Q/\mathbb{F}_q$ and $y_0 + y_1\alpha + \cdots + y_{b-1}\alpha^{b-1} \neq 0$ for $(0,\ldots,0) \neq (y_0,\ldots,y_{b-1}) \in \mathbb{F}_q^b$.

(II) For $\delta \in \mathbb{F}_Q^*$, $\sum_{x\in\mathbb{F}_Q^*} \chi(x)\zeta_p^{T_p^Q(\delta x)} = \overline{\chi}(\delta)G_Q(\chi)$.

Let $H = \{y_0 + y_1\alpha + \cdots + y_{b-1}\alpha^{b-1} : (y_0,\ldots,y_{b-1}) \in \mathbb{F}_q^b\}$. Then H is an $\mathbb{F}_q-$ subspace of $\mathbb{F}_Q$ with $\dim_{\mathbb{F}_q} H = b$. Moreover, $\mathbb{F}_q^* \subseteq H^* = H\backslash\{(0,\ldots,0)\}$ and H^* is a disjoint union of $\frac{q^b-1}{q-1}$ coset of $\mathbb{F}_q^*$ in $\mathbb{F}_Q^*$. Namely,

$$H^* = \mathbb{F}_q^* \times S = \{\delta s : \delta \in \mathbb{F}_q^*, s \in S\}$$

where S is a representative set of such $\frac{q^b-1}{q-1}$ cosets of $\mathbb{F}_q^*$ in H^*. By (3) we get

$$N_\beta = \frac{n}{q^b} + \frac{1}{eq^b} \sum_{\substack{\chi\in\widehat{\mathbb{F}_Q^*}\\ \chi(D)=1}} \overline{\chi}(\beta)G_Q(\chi) \sum_{y\in H^*} \overline{\chi}(y)$$

$$= \frac{n}{q^b} + \frac{1}{eq^b} \sum_{\substack{\chi\in\widehat{\mathbb{F}_Q^*}\\ \chi(D)=1}} \overline{\chi}(\beta)G_Q(\chi) \sum_{s\in S}\overline{\chi}(s) \sum_{\delta\in\mathbb{F}_q^*} \overline{\chi}(\delta)$$

$$= \frac{n}{q^b} + \frac{q-1}{eq^b} \sum_{\substack{\chi\in\widehat{\mathbb{F}_Q^*}\\ \chi(D)=\chi(\mathbb{F}_q^*)=1}} \overline{\chi}(\beta)G_Q(\chi) \sum_{s\in S}\overline{\chi}(s) \quad (4)$$

Since $D = \langle \gamma^e \rangle$ and $\mathbb{F}_q^* = \langle \gamma^{\frac{Q-1}{q-1}} \rangle$, we have $D\mathbb{F}_q^* = \langle \gamma^{e'} \rangle$ where $e' = \gcd(e, \frac{Q-1}{q-1}) = 1$ by assumption. Therefore the summation in the right-hand side of (4) remains only trivial character $\chi = 1$. We get $N_\beta = \frac{n}{q^b} - \frac{q^b-1}{eq^b} = \frac{Q-q^b}{eq^b}$ since $G_Q(\chi) = -1$ for trivial character $\chi = 1$, and $|S| = \frac{q^b-1}{q-1}$. Then $w_b(c(\beta)) = n - N_\beta = \frac{(Q-1)q^b - Q + q^b}{eq^b} = \frac{Q(q^b-1)}{eq^b}$ which is independent of $\beta \in \mathbb{F}_Q^*$. Therefore C is an equi-b-distance code with $d_b = \frac{Q(q^b-1)}{eq^b}$. From $n = \frac{Q-1}{e}$ and $K = q^k = Q$ we know that $d_b > n\theta_b (\theta_b = \frac{q^b-1}{q^b})$ and $K = d_b/(d_b - n\theta_b)$ which means that the code C for b-symbol channel meets the Plotkin-like bound given by Lemma 1. □

By taking $e = q-1$, the cyclic code C has parameters $[n, k, d_b]_q$ where $n = \frac{Q-1}{q-1}, k = s$ and $d_b = \frac{Q(q^b-1)}{(q-1)q^b}$. In fact, we can get more linear codes by shorten the code C with such parameters. Let $q - 1 = el$, then $n = \frac{Q-1}{e} = l \cdot \frac{Q-1}{q-1}$.
We consider the following linear code over $\mathbb{F}_q$

$$\widetilde{C} = \{\tilde{c}(\beta) = (T_q^Q(\beta), T_q^Q(\beta\alpha), \ldots, T_q^Q(\beta\alpha^{\tilde{n}-1})) \in \mathbb{F}_q^{\tilde{n}} : \beta \in \mathbb{F}_Q\} \tag{5}$$

where $\tilde{n} = \frac{Q-1}{q-1} = n/l$. Namely, we take $\widetilde{c}(\beta)$ as the first $\widetilde{n}$ components of $c(\beta)$. For any $t \geq 1$,

$$T_q^Q(\beta\alpha^{i+t\tilde{n}}) = T_q^Q(\beta\alpha^i)\alpha^{t\tilde{n}} \tag{6}$$

Since $\alpha^{t\tilde{n}} = (\alpha^{\tilde{n}})^t \in \mathbb{F}_q^* = \langle \gamma^{\tilde{n}} \rangle$. It is easy to see from (6) that for any b $(2 \leq b \leq s-1)$, $w_b(c(\beta)) = l w_b(\tilde{c}(\beta))$. Therefore $\tilde{d}_b = d_b(\tilde{C}) = d_b(C)/l = \frac{Q(q^b-1)}{(q-1)q^b}$, and $K = \frac{d_b}{d_b - n\theta_b} = \frac{\tilde{d}_b}{\tilde{d}_b - \tilde{n}\theta_b}$. We get the following consequence of Theorem 1.

Theorem 2 Let $Q = q^s, \mathbb{F}_q^* = \langle \gamma \rangle, q - 1 = el, \tilde{n} = \frac{Q-1}{q-1}, \alpha = \gamma^e$ and assume that $\mathbb{F}_q(\alpha) = \mathbb{F}_Q$ and $\gcd(e, \tilde{n}) = 1$ (namely, $\gcd(e, s) = 1$). Then for $2 \leq b \leq s-1$, the code $\tilde{C}'$ over $\mathbb{F}_q$ for b-symbol channel defined by (5) has parameters $[\tilde{n}, k = s, \tilde{d}_b]_q$ where $\tilde{d}_b = \frac{Q(q^b-1)}{(q-1)q^b}$ and meets the Plotkin-like bound.

Remarks (1) For $b \geq s$, $d_b(C) = n$ and $d_b(\tilde{C}) = \tilde{n}$.

(2) The linear code $\tilde{C}$ over $\mathbb{F}_q$ is a "constacyclic". Namely, if $(c_0, c_1, \ldots, c_{\tilde{n}-1}) \in \tilde{C}$ then $(c_1, \ldots, c_{\tilde{n}-1}, \delta c_0) \in \tilde{C}$ where $\delta = \alpha^{\tilde{n}} \in \mathbb{F}_q^*$.

(3) For the case $e' = \gcd(e, \frac{Q-1}{q-1}) \geq 2$, in order to determine $d_b(C)$ we need to compute the summation in the right-hand side of (4) for nontrivial character χ which might be difficult in general.
